Histopathology Report

DIAGNOSIS

Skin, midline dorsal thorax, mass excision: Carcinoma

Comment

While squamous differentiation is not appreciated in this mass, the close association with the epidermis and presence of intercellular junctions best support squamous cell carcinoma.

Microscopic findings

The moderately-defined, raised, plaque-like, superficial dermal mass causes segmental effacement of the epidermis. The mass is comprised of ovoid to polyhedral cells arranged singly and in clusters separated by hyalinized eosinophilic stroma. The cells have moderate amounts of cytoplasm, large round to plump oval nuclei, coarse reticular chromatin, and prominent nucleoli. Anisocytosis and anisokaryosis are moderate. The mitotic count is eight figures per ten high power fields (2.37 mm^2). Fine intercellular junctions are sometimes observed between cells arranged in clusters. The mass is infiltrated by scattered leukocytes, predominantly neutrophils. Epidermis compressed to the edges of the mass is hyperplastic. The mass does not extend to examined margins (about 1 mm from the nearest (deep) margin).

Gross description

The received haired skin specimen measured 1.2 x 0.9 x 0.5 cm and contained an approximately 1.0 x 0.8 x 0.3 cm mass. The mass was dark brown, nodular, and firm. Representative radial sections were taken and processed in 1A.

Clinical summary

2mo hx of focal, scabbed lesion, appr 6mm, on caudal dorsum; scab easily removed; cytology Accession - C22-2179-1

Differential diagnosis: r/o benign v malignant v infectious

Specimen containers received: 1

Cytology/Fluid Analysis Report

INTERPRETATION

Skin, midline, dorsal, abdomen, impression smear: Septic neutrophilic inflammation with squamous cell proliferation and atypia

Comments

The bacterial infection with cocci may be secondary rather than primary especially given that the lesion has a scab. The degree of squamous epithelial cell atypia is concerning. Differentials include squamous cell carcinoma, papilloma, and squamous hyperplasia with dysplasia secondary to inflammation. Histopathology is recommended for diagnosis especially if the lesion does not resolve with antibiotic administration.

Microscopic Description

The moderately cellular smears consist of many atypical squamous epithelial cells, degenerate neutrophils, lymphocytes, few spindle cells and macrophages that exhibit leukophagia in a bloody background. Many neutrophils contain phagocytized bacterial cocci. There are squamous-type, large polygonal or angular epithelial cells occurring singly and in clusters. The squamous cells exhibit moderate anisocytosis, anisokaryosis and occasional binucleation or trinucleation. The cells have moderately abundant vesicular to smooth pale blue cytoplasm and a medium ovoid central to eccentric hyperchromatic nucleus with variably prominent, often large, round to angular nucleoli. There are also numerous free nuclei and chromatin strands from ruptured cells in the background.

Clinical Summary

1 mo hx of 6mm raised, scabbed lesion on the caudal dorsum. scab was easily removed. (photo in file)

Differential diagnosis: r/o infectious v benign v malignant v other

Number of slides received: 2 skin

Specimen containers received: None received

Dear Nancy,

or as needed for diagnosis of illnesses

We are currently updating each monkey's medical record and would like to be sure that our health information on your monkey is both complete and up to date. We have noted the information that currently is in your monkey's file at this time. We would appreciate your assistance in verifying that this information is current and in providing the requested information for any of the following procedures that your monkey may have undergone (and that we currently do not have in your monkey's file). Please also note details of any additional surgical procedures, tests, illnesses or injuries that are not specified below. Additional paper or copies of your vet's records may be attached to provide details.
